

This document shows how the implemented AI powered profile consolidation and deviates from the original proposal. The idea was to create a agentic system that helps users in parsing their resume and linkedin profiles to extract meaningful information that can be fed to job applicators. While the project largely adhered to the proposed idea, issues cropped up in the implementation. The use of libraries like autogen that are relatively new and have limited support and documentation proved to be a difficult task and halted development time in a major way. Unfortunately, due to some time management issues and me working alone on this also contributed to the lateness in delivery of the project.
